Desorption

ABSTRACT

Mango stone biocomposite efficiency for the removal of phosphate ions (PO₄³⁻) from aqueous solution was investigated as a function of pH (2–8), biocomposite dose (0.05–0.40 g/100 mL solution), contact time (5–120 min), initial PO₄³⁻ ions concentration (20–800 mg/L) and temperature (33–61 °C). Maximum PO₄³⁻ ions removal was achieved at pH 2, biocomposite dose 0.3 g, contact time 90 min and initial PO₄³⁻ ions concentration 200 mg/L. At optimized conditions, up to 95 mg/g PO₄³⁻ adsorption was achieved. Biocomposite pre-treatment with surfactants (SDS, Tween-80, C-TAB, VIM and Surf excel) were also investigated and it was observed that surfactants pre-treatments decreased the adsorption capacity of the biocomposite. Thermodynamic study (ΔG°, ΔH° and ΔS°) revealed that PO₄³⁻ adsorption process onto biocomposite was spontaneous and endothermic in nature. Adsorption data fitted well to the Freundlich isotherm and pseudo-second-order kinetic model. Adsorbed PO₄³⁻ was successfully desorbed using 1.0 M NaOH solution. Results revealed that biocomposite adsorbed PO₄³⁻, which could possibly be used for the adsorption of PO₄³⁻ efficiently from wastewater.

1. Introduction

The waste discharged from agricultural, industrial and domestic domains contain significant amount of PO₄³⁻ ions which pollute the aquatic environment [1]. The PO₄³⁻ ions > 2 μM in water is harmful and is enough to disturb the natural food chain by stimulating the growth of algae (eutrophication) and also decrease dissolved oxygen (DO), which not only is lethal to aquatic organisms, but also change the quality of water reservoirs [2–4]. Hence, there is a need to develop efficient wastewater treatment technologies that eliminate the micropollutants from wastewater and PO₄³⁻ ions are not easy to remove through the conventional techniques. Different physical, chemical and biological methods have been developed for the treatment of wastewater containing PO₄³⁻ ions. The biological treatments is difficult to operation because aerobic and anaerobic conditions have to main for efficient treatment of wastewater and osmosis and electro dialysis have been developed for PO₄³⁻ ions removal which are efficient, but these methods are costly [5]. Also, these methods also generate sludge, which cause secondary pollution. Under the

current scenario of pollution [6–20], there is a need to develop green and eco-friendly methods for the remediation of pollutants. Biosorption is regarded as efficient remediation tool and is equally efficient for the removal of organic and inorganic pollutants [3,4,6,13,21–31]. More recently, researchers developed adsorbents, which are cheap, easily available and do not need special maintenance during operational conditions [32]. In this regard, biocomposite based on agro-industrial by-products such as peanut hulls, rice husk, orange peel and cotton sticks are proved to be highly efficient, recyclable and cost effective. Number of studies have been conducted and biocomposites have shown high potential for elimination of metal ions, inorganic ions, dye and other organic compounds from wastewater [33–38].

In view of efficiency of biocomposite for the removal of micro-pollutants, mango stone biocomposite was prepared and used for the removal of PO₄³⁻ ions. The pH, biocomposite dose, contact time, initial PO₄³⁻ ions concentration and temperature were optimized for maximum ions removal. Moreover, effect of surfactant pre-treatment of biocomposite on adsorption capacity was also explored. Adsorption data was modeled using different kinetic and isotherms models. Thermodynamic was also computed in order to evaluate the PO₄³⁻ ions adsorption nature using biocomposite.

2. Material and methods

2.1. Chemical and reagents

The reagents and chemical used were of analytical grade, i.e., potassium dihydrogen orthophosphate (KH₂PO₄), ferric chloride (FeCl₃), potassium borohydride (KBH₄), ethanol, sodium hydroxide (NaOH) and hydrochloric acid (HCl) were purchased from Sigma–Aldrich. Ultra-pure water with a resistivity of 18.2 MΩ cm from Milli-Q system (Millipore) was used for the preparation of solution throughout the study.

2.2. Biomass collection

Mango stone was collected from student market, University of Agriculture Faisalabad, Faisalabad, Pakistan. The mango stone extensively washed with water to remove particulate matter and dust and dried in open air followed by oven drying at 60 °C until constant weight. The dried mass was grinded (Moulinex, France), sieved (25 mm) and used for biocomposite preparation.

2.3. Biocomposite preparation

Mango stone powder (10 g) was mixed with 250 mL of FeCl₃, then, KBH₄ solution (±250 mL) was added drop wise with constant slow stirring. Here, KBH₄ acts as a reducing agent for the conversion of FeCl₃ to zero valent iron. After another 30 min stirring, the mixture was filtered; residue was extensively washed with ethanol (4 time, to remove un-reacted ions). Finally, the solid mass obtained was dried in oven at 60 °C for 24 h, grinded and passed through siever of 300 μ (OCT-DIGITAL 4527-01).

2.4. Biocomposites pre-treatment

The biocomposite was treated with different surfactants i.e., SDS, Tween-80, C-TAB, VIM and Surf excel. All surfactants solution (5%) was prepared and agitated with biocomposite for 1 h at 120 rpm in orbital shaker at 30 °C. After stipulated time period, the biocomposite was washed thoroughly with water and dried in an oven at 60 °C overnight [39] and used for adsorption process. Similar adsorption conditions were adopted both un-treated and surfactants pre-treated biocomposites.

2.5. Biosorption procedure

Stock solution of KH₂PO₄ (1000 mg/L) was prepared in distilled water and working concentrations were prepared by dilution. The pH of the solution was adjusted using 0.1 M NaOH and HCl solution. For batch biosorption experiments, pH 2–8, biocomposite dose 0.05–0.4 g/100 mL of solution, contact time 5–120 min, initial PO₄³⁻ ions concentration 20–800 mg/L and temperature 33–60 °C were investigated at fixed shaking speed of 120 rpm. Adsorption experiments were conducted in 250 mL flask taking 100 mL of PO₄³⁻ ions solution both for native biomass, surfactant pre-treated and un-treated biocomposites. After mixing of adsorbent with PO₄³⁻ ions solution and pH adjustment, flasks were covered with aluminum foil and set at 120 rpm in temperature controlled incubator shaker. After stipulated time period, the adsorbent was separated by filtration and residual PO₄³⁻ ions concentration was measured spectrophotometrically (CE Cecil 7200, UK) [40]. All experiments were carried out in triplicate, data was averaged and the adsorption capacity (mg/g) was estimated as shown in Eq. (1).

\[
q_e = \frac{(C_0 - C_e)V}{W}
\]

where \(C_0\) is the initial PO₄³⁻ ions concentration (mg/L), \(C_e\) is the equilibrium PO₄³⁻ ions concentration (mg/L), \(V\) is the volume of the solution (L) and \(W\) is the mass of the biocomposite (g).

2.6. Desorption study

Desorption of PO₄³⁻ ions was carried out using 0.1–1.0 M NaOH solution. The loaded biocomposite was mixed with NaOH solution and stirred at 120 rpm for 2 h. The biocomposite was separated from solution and PO₄³⁻ ions concentration was measured and desorption percentage was estimated using relation shown in Eq. (2) [29]. Where, \(q_d\) (%) is the percentage of PO₄³⁻ ions desorbed. \(D\) and \(R\) are representing the PO₄³⁻ ions adsorbed and desorbed, respectively.

\[
q_d(\%) = \frac{D}{R} \times 100
\]
PO₄³⁻ ions on to biocomposite. The equilibrium experimental data was fitted using Langmuir [43] and Freundlich [44] and Harkins-Jurra [45] isotherms.

2.8. Statistical analysis

The adsorption experiments were performed in triplicate and data was reported as mean ± SD. The regression coefficients (R²) values of isotherms and kinetics models were calculated using statistical functions of Microsoft Excel (version Office XP, Microsoft Corporation, USA).

3. Results and discussion

3.1. Optimization of process variables

The screening study was done between native and biocomposite biosorbent for PO₄³⁻ ions removal from aqueous solution and results are shown in Fig. 1. Result indicated that biosorbent had possessed high potential for elimination of PO₄³⁻ ions from wastewater as compared to native biomass. The optimization of process variables for the adsorption of PO₄³⁻ ions was done for biocomposite due to its higher efficiency. Initial pH plays an important role in biosorption of ions by affecting the charge on the surface of biosorbent, degree of ionization of functional groups and solution chemistry [46]. Removal of PO₄³⁻ ions using biocomposite was studied at a range of pH 2.0–8.0. The pH profile for PO₄³⁻ ions removal was studied using dosage of 0.1 g, initial PO₄³⁻ ions concentration of 50 mg/L at 33 °C for the contact time of 90 min and results are shown in Fig. 2A. From results, it was observed that the maximum biosorption capacity (60.1 mg/g) was achieved at pH 2 and after increasing pH, reduction in biosorption capacity was observed. The optimum pH was found to be 2. The higher removal of PO₄³⁻ at lower pH might be due to production of more positive active sites on biosorbent surface, which favors the biosorption because of creating electrostatic interaction among PO₄³⁻ and biosorbent surface [47]. Kose and Kivanc [48] found the same trend in PO₄³⁻ ions adsorption process using calcined waste egg shell. Previous studies also showed at the adsorption of PO₄³⁻ ions on to activated rice husk, fruit juice residue rice husk and fruit juice residue was highly pH dependent and adsorptions of PO₄³⁻ ions were maximum at pH 6 and by further increasing the pH beyond this values the adsorption capacities of PO₄³⁻ ions decreased and author correlated this behavior of PO₄³⁻ ions adsorption with pHpzc [49]. Similarly, La-modified clinoptilolite showed maximum adsorption in the pH range of 5.0–8.0 [50] and authors correlated this behavior with the formation of hydroxides. So far, under alkaline condition (pH > 8), the increased hydroxide ions would compete with PO₄³⁻ ions for the adsorption and resultantly, complexation of PO₄³⁻ ions suppressed and adsorbent capacity reduced.

The effect of biocomposite dose (0.05–0.4 g) on biosorption of PO₄³⁻ was studied at optimum pH 2, 50 mg/L of initial PO₄³⁻ ions concentration and temperature 33 °C. The results are shown in Fig. 2B. Results indicated that the adsorption capacity increased from 40.77 to 78.99 mg/g by increasing dose from 0.05 to 0.3 g/100 mL of solution and beyond this dose,
the adsorption did not increase and maximum removal was achieved at 0.3 g/100 mL of solution. The enhanced adsorption with biocomposite dose revealed the availability of active binding sites for PO₄³⁻ ions and the reduction beyond certain dose was due to overlapping of biocomposite particles, which reduced the contact between PO₄³⁻ ions and functional groups [51]. Similar results have been reported previously for the biosorption of PO₄³⁻ on to mine wastes [52].

Equilibrium time is an important parameter for designing of an economical system for the treatment of wastewater. The effect of contact time on adsorption was studied in the range of 5–120 min. The equilibrium was achieved in 90 min at pH 2.0, biocomposite dosage 0.3 g, initial PO₄³⁻ ions concentration 50 mg/L and 33 °C (Fig. 3A). The PO₄³⁻ ions adsorption was very fast initially which was due to accessibility of high number of vacant active binding sites. Later, the removal capacity of biosorbent was slowed down due to coverage of active sites and then equilibrium was reached with 90 min of contact time and at the time of 80.5 mg/g adsorption was observed. After achieving equilibrium, the effect of contact time was insignificant and this trend was in line with already reported studies [53]. Das et al. [54] also found the same trend in PO₄³⁻ ions removal from aqueous solution using double layered hydroxides. The initial PO₄³⁻ ions concentration gives information about driving force to reduce the diffusion mass transport resistance between adsorbate and biocomposite [29]. Adsorption capacity of biocomposite for the removal of PO₄³⁻ ions was studied in the initial concentration range of 20, 40, 60, 80, 100, 150, 200, 300 (mg/L) and results thus obtained are shown in Fig. 3B. Results showed the direct relation between biosorption capacity and initial PO₄³⁻ ions concentration, the PO₄³⁻ ions adsorption increased by increasing the concentration of PO₄³⁻ ions. The maximum removal of PO₄³⁻ ions was observed at 200 mg/L initial concentration. The highest amount of PO₄³⁻ ions taken up by biocomposite was 95 mg/g. The higher PO₄³⁻ ions uptake might be because of more probability of collision between PO₄³⁻ ions and biosorbent at higher initial PO₄³⁻ ions concentration. After coverage of all active binding sites, there was no increment in biosorption capacity was observed by increasing more initial PO₄³⁻ ions concentration [55]. Similar behavior was observed in a comparative adsorption study of PO₄³⁻ ions using different agricultural wastes [56].

Temperature is critical parameter that describes the feasibility and nature of biosorption process. Fig. 4 shows the removal of PO₄³⁻ ions from aqueous solution as a function of temperature (33–61 °C) using 0.3 g of biocomposite, pH 2, initial PO₄³⁻ ions concentration 50 mg/L and shaking speed 120 rpm. The optimum temperature was found to be 54 °C. Results demonstrated that the biosorption process was endothermic in nature because significant increment in PO₄³⁻ ions removal was observed as the temperature was increased from 33 to 61 °C. The reason behind such increment might be due to more interaction between PO₄³⁻ ions and biosorbent functional binding active sites because of high kinetic energy at high temperature [57]. Namavivayam and Prathap [58] investigated that the biosorption of PO₄³⁻ ions by Fe(III)/Cr(III) hydroxide and adsorption was endothermic of PO₄³⁻ ions.

first-order and pseudo-second order kinetic models are given in Eqs. (3) and (4).

\[
\log(q_e - q_t) = \log q_e - K_1 \cdot \frac{t}{2.303}
\]  

(3)

where \( q_e \) (mg/g) is the biosorption capacity at equilibrium, while \( q_t \) (mg/g) is the biosorption capacity at time \( t \). The \( k_2 \) (g/mg min) is the pseudo-second-order rate constant. \( k_2 \) was be calculated from the intercept by plotting \( t/q_e \) against \( t \). The values of kinetic parameters are given in Table 1. The pseudo-second-order kinetic model was found to be well fitted to the \( PO_4^{3-} \)-ions adsorption data. The \( R^2 \), experimental and calculated biosorption capacity values were more reliable in case of pseudo-second order kinetic model as compared to pseudo-first order kinetic model. So far, the \( PO_4^{3-} \)-ions followed second-order kinetic model since the \( q_e \) value determined experimentally was in agreement with the calculated value. Moreover, the \( R^2 \) value was also higher in case of second-order kinetic model.

### 3.4. Equilibrium modeling

The equilibrium experimental data was fitted into linear forms of three isotherms namely Langmuir, Freundlich and Harkins-Jura. The mathematical form of Langmuir isotherm [43] is shown in Eq. (5):

\[
\frac{C_e}{q_e} = \frac{1}{q_m b} + \frac{c_e}{q_m}
\]  

(5)

where \( C_e \) (mol/L) is the \( PO_4^{3-} \)-ions concentration at equilibrium, while \( q_e \) (mg/g) is the biosorption capacity. \( b \) is the biosorption binding energy and \( q_{max} \) (mg/g) is monolayer biosorption capacity.

The Freundlich isotherm relation is shown in Eq. (6) [44].

\[
\log q_e = \log K_F + \frac{1}{n} \log C_e
\]  

(6)

where \( K_F \) (mg/g) and \( 1/n \) are the Freundlich constants and these represented the biosorption capacity and biosorption intensity, respectively, which were calculated from intercept and slope by plotting the graph between \( \log q_e \) and \( \log C_e \).
(mg/g) is the amount of PO₄³⁻ ions biosorbed per unit biocomposite.

The Harkins-Jurka isotherm linear form is shown in Eq. (7) [45].

\[
\frac{1}{q_e^2} = \left( \frac{B}{A} \right) - \left( \frac{1}{A} \right) \log C_e
\]  

(7)

where A and B are the Harkins-Jurka isotherm constants. The calculated values of PO₄³⁻ ions adsorption on to biocomposite for different isotherms are given in Table 2. Among these three isotherms, Freundlich showed the best fitness which explained the formation of multilayer of PO₄³⁻ ions on the surface of biocomposite. The R² values in case of Freundlich isotherm was considerably higher versus other two isotherms. The qe value determined experimentally was also in agreement with calculated qe value in case of Freundlich isotherm. So far, the Freundlich isotherm showed best fitness for the adsorption of PO₄³⁻ ions on to the biocomposite. The Freundlich isotherm describes the sorption of PO₄³⁻ ions was occurred on heterogeneous surfaces and multilayer adsorption was favorable. It assumes that the uptake of adsorbate ion occurs on a heterogeneous adsorbent surface. The Freundlich isotherm also describes an empirical relation that the stronger binding sites were occupied first and binding strength decreased by increasing the degree of binding sites occupation [31].

3.5. Thermodynamic study

Temperature effect on removal of PO₄³⁻ ions using biocomposite was studied in the temperature range of 306–334 K and changes in standard enthalpy (ΔH°), standard entropy (ΔS°), and Gibbs free energy (ΔG°) were calculated as shown in relations (8) and (9).

\[
\ln(K_d) = \frac{\Delta S°}{R} - \frac{\Delta H°}{R} \times \frac{1}{T}
\]  

(8)

\[
\Delta G° = -RT \ln(K_d)
\]  

(9)

where K_d is the coefficient of distribution and it was calculated using the expression K_d = qe/Kc. °T represents the temperature in Kelvin (K) and R is the universal gas constant. The value of ΔH° (kJ/mol) and ΔS° (kJ/mol K) were calculated from slope and intercept by plotting the ln K_d against 1/T. From thermodynamic study, it was observed that the process for the removal of PO₄³⁻ ions using biocomposite was endothermic in nature. The high value of entropy indicating the ordering of system as biosorption process was proceeded. The value of ΔG° (kJ/mol) represented the degree of non-spontaneity of biosorption process and it was reflected energetically favorable because its value was increased with rise of temperature (Table 3).

3.6. Desorption study

The biomass used in biosorption should be reused to make the process attractive, efficient and economical. For desorption, selection of efficient eluent is important. Desorption depends on the biosorption process, biosorbate and biosorbent can be recovered and regenerated, respectively. Since the adsorption was efficient at low pH value, so the desorption was studied using basic solution. NaOH (0.2–1.0 M) was used for the desorption of PO₄³⁻ ions [60] from loaded biocomposite. It was noted that PO₄³⁻ ions was desorbed efficiently at higher concentration of NaOH (Fig. 5B). Desorption of PO₄³⁻ ions was achieved up to 82% using 1.0 M NaOH. Overall, the biocomposite showed promising efficiency for the adsorption and desorption of PO₄³⁻ ions and could possibly be used for the removal of PO₄³⁻ ions from industrial wastewater.

4. Conclusions

Biocomposite was prepared from mango stone and used for the removal of PO₄³⁻ ions from aqueous solution. The process variable such as pH (2–8), biocomposite dose (0.05–0.40 g/100 mL solution), contact time (5–120 min), initial PO₄³⁻ ions concentration (20–800 mg/L) and temperature (33–61 °C) were optimized for maximum PO₄³⁻ ions adsorption. The PO₄³⁻ ions adsorption was achieved up to 95 mg/g at pH 2, biocomposite dose 0.3 g, contact time 90 min and initial PO₄³⁻ ions concentration 200 mg/L. The biocomposite pre-treatments with surfactants (SDS, Tween-80, C-TAB, VIM and Surf excel) decreased the adsorption capacity of the biocomposite. Adsorption data fitted well to the Freundlich isotherm and pseudo-second-order kinetic model. The thermodynamic study revealed that the PO₄³⁻ ions adsorption process was spontaneous and endothermic in nature. Biocomposite showed promising adsorption efficiency, which could possibly be used for the adsorption of PO₄³⁻ ions from wastewater and this biocomposite is also extendable to other inorganic ions sequestration from wastewater.
